Abstract

Background: Healthcare digital transformation should focus on the use of innovative technologies to enhance quality, safety, efficiency of care services, and patient experience. Subsequently, the roles and skills of healthcare staff will change, requiring evaluation and elevation of digital literacy across the physiotherapy profession. **Aim:** To evaluate the confidence, motivation and competence of digital technologies in a cohort of UK physiotherapists (juxtaposed with a wider group of allied health professionals). **Methods:** A quantitative, cross-sectional online questionnaire of physiotherapists and other allied health professionals (AHPs) in the UK. **Results:** 282 responses from AHPs were received with 279 complete responses for further analysis (including 126 physiotherapists). Physiotherapists report moderate-high levels of confidence in the use of digital devices (7.6 ± 1.77), and high levels of motivation in learning about digital technology (8.7 ± 1.6). Physiotherapists self-rate their knowledge regarding the benefits of digital transformation as high (72%). Physiotherapists show a strong preference for daily communication via telephone (82%) and email (97%). **Conclusion:** Physiotherapists demonstrate moderate-high levels of confidence and motivation to use digital technologies (in line with those seen in other AHPs). Higher degrees of competence are reported regarding understanding the benefits of digital technology, and lower competence is reported regarding topic areas such as artificial intelligence and data analytics.

Introduction

In 2016, Professor Robert Wachter, made recommendations highlighting the need for a thoughtful, long-term strategy for NHS digital transformation, focusing on using technology as a means to enhance quality, safety, efficiency and patient experience (Wachter, 2016). In 2019, The Topol Review “Preparing the healthcare workforce”, illustrated how innovative technologies may alter the roles of clinical staff in the next two decades (Topol, 2019). It mapped the skills required to ensure safe, effective and personalised care for patients, and identified gaps which could be filled by alternate professions, or via training and development of current and future staff. In support of the vision for digitally-enabled care in the NHS Long Term Plan (NHS England, 2019a), the review recommends raising digital literacy amongst the current workforce, and the development of knowledge, skills and behaviours to facilitate staff confidence and competency. Organisations are advised to invest in building digital skills within their workforce, and recommend that all staff are trained in health data management, critical appraisal and

ethics of artificial intelligence (AI) and automated technologies.

Digital readiness

While the need to upskill healthcare staff has been documented (NHS England, 2019; Topol, 2019; Wachter, 2016), the mechanism by which education can influence digital implementation remains unclear (Cornford, Klecun & Lichtner, 2014; Hilberts & Gray, 2014). Workforce development is essential to ensure that the benefits of technology materialise on implementation (Greenhalgh et al., 2017). Health Education England’s Technology Enhanced Learning Programme, and The Building a Digital Ready Workforce programme of the National Information Board, developed the Health and Care Digital Capabilities Framework (Health Education England, 2018). They define digital literacy as “the capabilities that fit someone for living, learning, working, participating and thriving in a digital society.” The framework divides digital literacy into domains of capability by which individuals can be assessed, including communication, data and technical proficiency.

In the Timmus project, Newman, Church and Beetham (2019) investigated the use of digital diagnostic tools to evaluate the digital capabilities of NHS staff, and found that measurement of digital “willingness” (confidence and motivation) is largely successful. However, evaluation tools fail to reliably measure digital “experience” (environment, specific competence within professional roles). They suggest that measurement of competency should focus on the local context of environment and professional role to have meaning (Newman et al., 2019). Work developing profession-specific competency guidance has begun in postgraduate medical education, indicating that 42% of health informatics knowledge domains are not present in UK-based postgraduate curricula (Jidkov et al. 2019). In 2019, NHS England published the Allied Health Professional (AHP) Digital Framework, providing guidance for AHPs to develop digital competence at individual, department and organisational levels (NHS England, 2019b). It supports the planning and delivery of training in digital capabilities in order to evolve services into digitally mature and data-enabled entities. The facilitation of digital readiness, competence and literacy in all AHPs is key to this strategy. With a dearth of guidance as to how digital education should be guided for AHPs (and specifically physiotherapists), a two part project was commenced.

The first stage (described here) was a UK-wide survey of digital confidence, motivation and experience within AHPs, using the same question framework utilised by the Timmus project (Newman et al., 2019). Additionally, this survey asked respondents to self-rate their perceived competence relative to a preliminary competency framework, devised from the HEE digital capabilities (Health Education England, 2019) and the NHS England AHP Digital Frameworks (NHS England, 2019b). The results for physiotherapists will be presented, alongside those from the wider AHP cohort, to guide future workforce education and development. The second stage (not described here) is a Delphi study to elaborate on and ratify the preliminary competency framework used in this survey.

Methods

Design

This study used a quantitative, cross-sectional design. The questionnaire was constructed in 4 parts:

1. Respondent characteristics
2. Self-rating of confidence, motivation and experience (3 numerical rating scale questions, reproduced with permission from Timmus (Newman et al., 2019). Anchor descriptors were devised (0- None, 1-3- low, 4-6- moderate, 7-9- moderate-high, 10- high).

- a. How confident are you at using digital devices and software at work?
 - b. How motivated are you to learn how to use new digital devices and software at work?
 - c. How much experience do you have at using a variety of digital devices and systems at work?
3. Self-rating of perceived competence in digital competencies (93 competencies over 10 domains, 5 point Likert scale from Very poor to Very good)
 4. Description of current digital capability (11 questions, 1 question rating the degree of support provided by the host organisation, numerical rating scale (0-10), and 10 questions recording the frequency of digital activity categorically (Daily – Never).

Participants

Practising AHPs (including physiotherapists) from the UK were invited to complete an online survey. The survey was open to all 14 allied health professions recognised by the UK Health and Care Professions Council. The survey was disseminated via social media, as well as a blog post describing the objectives of the project. The NHS England-facilitated AHP Digital Network, and professional groups (e.g. the CSP Digital and Informatics Physiotherapy Group, the Scotland Digital Nursing, Midwifery and Allied Health Professional network, and the Northern Ireland Digital AHP group) were used as a further means of dissemination. This author’s host organisation was a final source of recruitment. Survey responses were collected from 10th July 2019 to 30th November 2019 (143 days). All responses were anonymous.

Data analysis

Descriptive analysis was undertaken for all respondent characteristics, self-rating of competence, and recording of frequency of activity data. Response percentages in the Likert scale categories of the physiotherapy cohort are compared with the results from AHPs. For the mean average self-rating scores for digital confidence, motivation, experience and organisational support, standard deviations were calculated and a Student’s T-test has been used to calculate the degree of statistical significance between the cohorts.

Ethical review was undertaken internally as part of the governance and quality assurance process within the author’s host institution. Anonymisation of responses was used to protect the identities of respondents.

Results

282 responses from AHPs were received, with 279 complete responses suitable for data analysis.

Respondent profile

Figure 1a¹ illustrates the profile characteristics of the respondents. 45% of respondents (n=126) were physiotherapists, 55% (n=153) were other AHPs. Figures 1b-e illustrate characteristics of the physiotherapists regarding experience (relative to the UK NHS Agenda for Change payment band system), work setting and location. 44% of respondents were band 8-9, with 50% of respondents between band 5-7. 30% of respondents worked in an inpatient hospital setting, 23% in outpatient clinics, and 14% within the community. 51% of respondents worked in London, England. 9% were situated in Scotland, and 3% were from Northern Ireland.

Self-rating of confidence, motivation, and experience

Table 1 summarises the self-rating of confidence, motivation and experience of digital technologies. Physiotherapists show moderate-high levels of confidence in the use of digital devices (7.6 ±1.77), and high levels of motivation in learning how to use technology (8.7 ±1.6). No statistically significant differences were found with the AHP cohort. AHPs showed a slightly greater rating of experience in using a digital technology at work.

	Physiotherapy (n=126)	AHP (n=153)	
	Mean (SD)	Mean (SD)	p=
Confidence	7.6 (1.77)	7.79 (1.76)	0.38
Motivation	8.7 (1.6)	8.75 (1.45)	0.81
Experience	6.96 (1.94)	7.3 (1.75)	0.13

Table 1: Self-rating of confidence, motivation and experience of digital technologies as per a 10 point numerical rating scale

Self-rating of competence

Table 2 (placed at the end of the article) illustrates the rating of perceived competence in various digital competencies. The results are grouped into positive (Good to Very good knowledge or ability), neutral (Fair), and negative ratings (Poor to Very poor). The results presented cover the most pertinent competency areas

relative to the Topol Review Recommendations (Topol, 2019) and the AHP Digital Framework (NHS England, 2019b).

Figures 2a-b show the self-rating for competencies rated to knowledge and understanding of digital. Both groups show high positive ratings of knowledge associated with the benefits of healthcare digital transformation (72% physiotherapy and AHP), and data protection/privacy regulation (70% physiotherapy, 68% AHP). Knowledge of clinical coding in electronic health records (e.g. SNOMED CT) is rated positively by only 18% of physiotherapists. In line with recommendations advising up-skilling of workers on AI (Topol, 2019), physiotherapists reported only a 10-15% positive rating in this area. Across three competencies associated with machine learning (ML)/AI, 68-72% of physiotherapists reported Poor to Very poor understanding. Two thirds of knowledge-based competencies showed ratings of Poor to Very poor understanding in greater than 30% of physiotherapists, demonstrating broad lack of knowledge in variable areas of digital capability. Similar findings are seen in the AHPs.

Figures 2c-d show competencies associated with the ability to perform digital tasks. The highest positive ratings by physiotherapists (Good to Very good ability to perform task), are the ability to perform a self-evaluation of their digital literacy (63%), and the ability to capture data in electronic health records (43%). These results are similar to the AHP cohort. The lowest rated abilities by physiotherapists were associated with using an electronic medicines management system (10%), data collection via wearable technology (19%), and the development of virtual patient clinics (20%). Whilst medicines management may fall outside of the scope of practice for many physiotherapists, the collection of data via linked, interoperable hardware, and the use of virtual clinics to enhance accessibility are both strongly featured in the NHS Long Term Plan (NHS England, 2019a) and the Topol Review (Topol, 2019). 10/11 skill-based competencies showed greater than 30% of the physiotherapy cohort describe their ability as Poor to Very poor (including data analytics, mHealth app prescription, and virtual care). Similar practical deficiencies are seen in the AHP cohort.

Description of current digital capability

Respondents rated how supportive their organisation was in the workforce development of digital skills. Physiotherapists had a mean average rating of 6.05/10 (±2.33), with AHPs rating 6.5/10 (±2.3) (p=0.11). Thus indicating that professionals consider their

¹ All figures placed at the end of the article, owing to their size.

organisations to be supportive of digital training to a moderate-high level. Digital capability was estimated by the frequency of activities being undertaken. Figure 3a shows that 72% of physiotherapists analyse patient data longitudinally on a monthly basis or greater (66% AHP).

Between-group similarities also exist for the use of voice recognition to dictate clinical records, with both groups stating this is never undertaken (75% physiotherapy, 74% AHP). Differences between groups are seen in the application of medical devices daily (19% physiotherapy vs 7% AHP). 65% of AHPs saying they never undertake this activity (40% for physiotherapy).

Figure 3d shows the physiotherapy results for the selected skills showing that 40% report they never undertake these activities.

Communication methods

Figures 4a-g compare the communication preferences of physiotherapists versus AHPs. Figure 4h shows only physiotherapist preferences. Physiotherapists had a substantial preference to use institutionally-secure (NHS/Trust) email for daily communication (97%). Telephone was also used daily (82%). AHPs showed similar findings with 91% daily frequency for email, and 82% for telephone. 82.53% of physiotherapists reported never using fax machines (67% AHPs). Video calling platforms were used by 45% of physiotherapists on a monthly basis or greater (43% AHPs), however, 50% of physiotherapists never used this mode of communication. Other methods were used at variable rates, including 73% using WhatsApp (69% AHPs). Only 18% used Slack (13% AHPs) and 16% used Microsoft Teams (20% AHPs).

Discussion

To the best of this author's knowledge, this is the first study evaluating the confidence and motivations of physiotherapists, juxtaposing their perceptions of competence, regarding digital knowledge and skills. Further, the frequency of undertaking specific digital tasks is described.

Confidence, motivation and experience

The levels of confidence and motivation reported by physiotherapists in this study are similar to those reported previously in the Timmus study (Newman et al., 2019). Whilst, Newman et al. (2019) found that confidence and motivation are important in describing digital capability, measuring experience

was inhibited by the diversity of roles both within and between professions. They suggest that confidence and motivation ("digital willingness") are as important as experience when considering engagement with digital technology.

Competency

Whilst confidence and motivation were sufficiently high to suggest engagement with digital technology, competence was variable across the profession. This may be a secondary consequence of amalgamating the results of all physiotherapists independent of their speciality roles. It may be that a musculoskeletal outpatient physiotherapist may require engagement with some areas of technology, not relevant to a critical care physiotherapist, and vice versa. It is pertinent to consider how digital transformation may influence practice specifically due to the needs of the role, and when there are likely transferable themes relevant to all. Two such competency areas, deemed vital components of digital competency by the guiding literature both in the UK and abroad, are machine learning/AI, and health informatics (Baker, Charlebois, Lopatka, Moineau & Zelmer, 2016; Bilimoria et al. 2019; Jidkov et al. 2019; NHS England, 2019; Topol, 2019). The self-rated competence of physiotherapists in these areas was low, despite the consensus that these are highly pertinent areas of workforce advancement. As such, whilst other foundational areas of competence are important, these areas have been chosen for further elaboration.

Machine learning / artificial intelligence

AI is a term used to describe the ability of a computer to perform tasks, which if performed by a human, one would consider intelligent. Machine learning (ML) is a subfield of AI where computers are trained how to learn without being explicitly programmed (Samuel, 1967). Physiotherapists in this study report their knowledge regarding AI/ML as Poor to Very poor across two areas: AI/ML used in diagnostic systems, and AI/ML for decision-support. These results were similar to AHPs. Ooi et al. (2019) evaluated the attitudes of radiologists regarding AI/ML. Their survey (n=125) found that 64.8% of respondents viewed themselves as novices regarding AI/ML, with 76% planning to include the topic within future personal development. This shows that the perception of competence in a professional group with greater exposure to AI/ML is similar to physiotherapists. The development of training standards in radiology for AI/ML is in the nascent stages. In both the USA and UK, standards require training radiologists to understand basics of imaging informatics (e.g. data privacy, post-processing imaging) (American Board of Radiology (2019).

Kolachalama and Garg (2018) suggest that concerning AI/ML, curricula should aim for literacy, rather than proficiency, focusing on developing conceptual knowledge to assist clinical

practice. Physiotherapy education could follow, by embedding technological knowledge relevant to patient care into workforce development strategies. Undergraduate training should include basic principles of AI/ML, illustrated via simulated cases, alongside the theoretical principles of benefits, risks and ethics. Thus supporting experiential learning in practice. Proficiency with advanced programming skills should be reserved for postgraduate training (Kolachalama & Garg, 2018).

Informatics / data analytics

Health informatics (i.e. clinical/medical informatics) is an interdisciplinary field concerning the use of biomedical data to improve individual and wider-population health (Kulikowski et al. 2012; Wyatt & Liu, 2002). It involves analysing data to guide evidence-based practice (Otero, Hersh & Ganesh, 2014). Systems are being developed which capture, analyse and apply data from various sources (e.g. genomic, public health, electronic health record (EHR) data) at a rate which is unsustainable for the healthcare workforce (Raghupathi & Raghupathi, 2014). However, there is little discussion of how practitioners will be supported in the use of this data, and how education may prevent the NHS workforce from “drowning in data” (Otero et al., 2019).

Physiotherapists report inconsistent knowledge and abilities in areas concerning data management, including tasks such as clinical coding and key aspects of data analytics. Reduced competence in the area of data management can subsequently lead to incorrect manual recording (e.g. structured data stored as unstructured clinical notes), leading to difficulties in searching and analysing patient data. Such issues perhaps underpin the irregular use of data for longitudinal analysis by physiotherapists. The results indicate a willingness and motivation to undertake informatics activities but variability exists in competency across the profession.

Clinicians express discomfort in understanding statistics (Krouss, Croft & Morgan, 2016), often seen as a barrier to translating research into practice by physiotherapists (Janssen, Hale, Mirfin-Veitch & Harland, 2016). Educational programmes should include concepts of data analytics beyond simple statistics (Otero et al. 2014). Informatics is a broader domain concerned with understanding types of data, evaluating its quality for specific tasks, and manipulation of data to leverage patient benefit (Dhar, 2013). It is likely that breadth and depth of training may be variable across the workforce, with greater depth for those demonstrating sufficient aptitude (Dhar, 2013).

Current capability

Capability is estimated based upon the frequency by which digital activities are undertaken. Even affordable, mature digital tools (such as voice recognition) show low levels of use by

physiotherapists. This low engagement is contradictory to the confidence and motivation described by the physiotherapy cohort, and may suggest that barriers, such as lack of EHR system interoperability, are inhibiting the use of such tools. This could explain the infrequent use of digital medical devices in practice and would indicate that structure and functionality of EHR systems should be examined to ensure it does not constrain the practical application of technology. Physiotherapists should engage with EHR system development to ensure it meets the needs of practice.

Current communication preferences

The NHS has been aiming to become paperless (Macaulay, 2016), with Health Secretary Matt Hancock aiming to “axe the fax” (Department of Health and Social Care, 2019). The communication preferences described by physiotherapists thankfully indicate common use of telephone and institutional email, as opposed to fax machines. There are also low rates around the use of alternative digital communication platforms (e.g. online video conferencing or instant messaging services, such as Slack or Microsoft Teams).

However, in response to the worldwide COVID-19 pandemic in 2020, it may be that these preferences changed significantly. For example, Microsoft Teams, a secure instant messaging and audio/video calls platform, was made available for free for NHS workers for a limited time during the outbreak (NHS Digital, 2020). Furthermore, NHSX provided guidance elaborating on information governance and use of digital platforms to share data during the unique circumstances with the pandemic (NHSX, 2020). Freedom to use digital tools (e.g. WhatsApp) was expanded for clinical communication where the “benefits outweigh the risks” (Digital Health London, 2020).

Both internal organisational communication, and patient-therapist interaction were largely transitioned to digital to optimise social distancing. Use of video conferencing platforms (e.g. Zoom or Attend Anywhere) were rapidly and widely adopted. Consequently, the Chartered Society of Physiotherapy published a guide for the rapid implementation of remote consultations (Chartered Society of Physiotherapy, 2020). How enforced transition to digital care alters the behaviours of clinicians beyond COVID-19 remains to be seen. It is likely that evolution towards enhanced digital literacy and, in particular, remote consultation and digital communication, remains a legacy of the pandemic. However, there is likely to be variability in which tools are used.

Limitations

These results are limited by the failure to subgroup respondents by age or gender. Increasing age has been associated with reduced digital literacy and lesser likelihood of using digital tools (Antonio & Tuffley, 2015). Analysing the impact of age

may have assisted the development of guidance relative to the varied needs of different age groups. Similarly, capability may present differently between genders. Whilst actual digital skills may not differ between men and women, the self-perception of women's capabilities may be lower than men's (Martínez-Cantos, 2017; van Deursen & van Dijk, 2015), which may subsequently impact their inclusion with digital technologies.

The online recruitment process used may have led to sampling bias in respondents who already have greater digital literacy, perhaps skewing results towards higher ratings of knowledge and competence. This was counteracted by sharing the survey internally to the author's home organisation. However, this may also have led to similar bias due to professionals sharing the same environment. The percentage of the sample who were physiotherapists was 20% higher than the distribution of physiotherapists within the larger body of AHPs in UK practice (26%) (Health and Care Professions Council, 2020). This may suggest physiotherapists were more likely to complete an online survey than other professions (and suggest higher rates of digital confidence).

Another limitation is that the framework used for self-assessment has not yet been ratified by independent AHP groups. Whilst published frameworks of digital literacy were used to construct the competencies, it remains appropriate to have the framework validated for appropriateness to each profession. Further, the digital tools which respondents were questioned about is not an exclusive list of tools where individuals can demonstrate competency. Rather, the most commonly used tools have been used to present an example of current digital skill levels. As such, this data will be biased to these author's choices.

Conclusion

Physiotherapists demonstrate moderate-high levels of confidence and motivation to use digital technologies, with variability within and between experience levels and professional roles. The results give a snapshot of a spectrum of digital literacy (knowledge and skills), which, despite not being exclusive, does provide a measure of the current state of digital capability across the profession. Higher ratings are shown for knowledge associated with theoretical underpinnings of digital transformation and associated policies, and lower ratings for digital skills in practice, and more advanced topics such as AI/data analytics.

Table 2: Self-reported competence (Physiotherapists vs AHPs).

		Physio (n=126)			AHP (n=153)		
	Good - Very good	Fair	Poor	Good - Very good	Fair	Poor	
Awareness of benefits of digital transformation for own profession and wider NHS	91 (72%)	25 (20%)	10 (8%)	110 (72%)	28 (18%)	15 (10%)	
Ability to undertake a self-evaluation of digital literacy	79 (63%)	35 (28%)	12 (9.5%)	90 (59%)	47 (31%)	16 (10%)	
Understanding of the Data Protection Act and risks associated with data privacy	88 (70%)	32 (25%)	6 (5%)	104 (68%)	40 (26%)	9 (6%)	
Ability to evaluate data type/quality towards effective searching and analytics	37 (29%)	46 (36.5%)	43 (34%)	43 (28%)	56 (37%)	54 (35%)	
Ability to capture structured & unstructured patient data in the electronic health record (EHR)	54 (43%)	33 (26%)	39 (31%)	71 (46%)	50 (33%)	32 (21%)	
Understanding of clinical coding terminologies (e.g. SNOMED CT) within the EHR	25 (19%)	29 (23%)	72 (57%)	28 (18%)	47 (31%)	78 (51%)	
Knowledge of digital tools which support the transfer of patient information at point of referral, admission, handover or discharge.	35 (28%)	57 (45%)	34 (27%)	45 (29%)	54 (35%)	54 (35%)	
Ability to use electronic systems for efficient medicines management	13 (10%)	20 (16%)	93 (74%)	23 (15%)	25 (16%)	105 (69%)	

Tack, C. (2020). Digital confidence, experience and motivation in physiotherapists: A UK-wide survey. OpenPhysio.

Understanding of digital tools which support visibility, requesting and resulting of testing (laboratory/pathology and medical imaging)	33 (26%)	45 (36%)	48 (38%)	43 (28%)	30 (20%)	80 (52%)
Knowledge and understanding of machine learning and artificial intelligence innovations within digital diagnostic systems	19 (15%)	22 (17%)	85 (64%)	25 (16%)	24 (16%)	104 (68%)
Knowledge and understanding of local organisational performance measurement systems	32 (25%)	33 (26%)	61 (48%)	40 (26%)	37 (24%)	76 (50%)
Knowledge and understanding of digital tools to advise practice through evidence-based guidelines to direct a patient pathway	29 (23%)	35 (28%)	62 (49%)	42 (27%)	40 (26%)	71 (46%)
Knowledge and understanding of machine learning and AI algorithms underpinning clinical decision-support system tools within healthcare digital systems	14 (11%)	21 (17%)	91 (72%)	19 (12%)	37 (24%)	97 (63%)
Knowledge and understanding of the development and/or evaluation of clinical decision-support systems which utilise machine learning and AI	13 (10%)	22 (17%)	91 (72%)	18 (12%)	36 (24%)	99 (65%)
Ability to identify non-clinically assured/inaccurate online health and care information	46 (36%)	34 (27%)	46 (36.5%)	62 (41%)	43 (28%)	48 (31%)

Tack, C. (2020). Digital confidence, experience and motivation in physiotherapists: A UK-wide survey. OpenPhysio.

Ability to recommend or prescribe a mobile health application	34 (27%)	41 (32.5%)	51 (40%)	41 (27%)	42 (27%)	70 (46%)
Ability to view and/or capture patient data at the point of care (via hand held device, wearable technology or connected medical device)	24 (19%)	27 (21%)	75 (59%)	31 (20%)	35 (23%)	87 (57%)
Ability to develop virtual clinics for direct patient care (using digital media as an alternative to face-to-face consultation)	25 (20%)	23 (18%)	78 (62%)	29 (19%)	42 (27%)	82 (54%)
Knowledge and understanding of the benefits of virtual clinics using secure platforms to provide consultations	38 (30%)	33 (26%)	55 (44%)	52 (34%)	47 (31%)	54 (35%)
Capacity to use digital technologies as required within quality improvement programmes with own local organisation	51 (40%)	32 (25%)	43 (34%)	56 (37%)	47 (31%)	50 (33%)
Capacity to identify the needs and requirements of the healthcare institution to guide a strategic programme of digital transformation	35 (28%)	38 (30%)	53 (42%)	37 (24%)	41 (27%)	75 (49%)
Capacity to direct the research agenda for own department towards topics of digital therapeutics, mobile health and digital transformation	34 (27%)	35 (28%)	57 (45%)	41 (27%)	35 (23%)	77 (50%)
